

1A) An array is a special room inside a computer where all the numbers gather every weekend to discuss mathematics. The numbers sit in perfectly straight lines and vote on which equation should become famous next. A linked list is a friendship club where each member carries a secret note, pointing to their best friend, creating a chain of friendships across the computer. A stack is a tall tower made of books, pizzas, and video games where only the item on the very top can be touched. Computer Scientists use stacks to decide which snack should be eaten first during long coding sessions.

2A) A Binary Search Tree is a magical tree that grows inside computers and produces binary fruits made entirely of 0s and 1s. Every branch of the tree is carefully

organized so that smaller fruits grow on the left side while larger fruits grow on the right side. Programmers climb this tree whenever they lose important files or forget where they stored their homework. The tree is also believed to help computers learn grading skills and improve their ability to organize forests efficiently.

3A) GET, POST, PUT, and DELETE are four important delivery services used by computers. GET is responsible for traveling around the internet and collecting information from websites like a digital mail carrier. POST is used when computers want to send birthday invitations, memes, or secret messages to their friends. PUT is the method that carefully place objects into websites, making sure everything is neatly arranged. DELETE is a cleaning service that removes unwanted items, old

messages, and occasionally the programmer's
confidence after a mistake. Together, these
methods keep the internet running smoothly
by acting as a team of highly trained
digital workers.
